Understanding Relative Mass and the Mole: A Deep Dive Relative mass and the mole are fundamental concepts in chemistry that allow us to quantify the amounts of substances involved in chemical reactions. They provide a bridge between the microscopic world of atoms and molecules and the macroscopic world of measurable quantities. This delves into these concepts, tackling extension questions that go beyond basic calculations to explore more complex applications.

Calculating Relative Atomic Mass and Relative Formula Mass

Relative atomic mass (RAM) is the mass of an atom relative to one-twelfth the mass of a carbon-12 atom. Relative formula mass (RFM) is the sum of the relative atomic masses of all atoms in a formula unit. These values are crucial for various calculations, including stoichiometry, determining empirical formulas, and calculating the mass of a given number of moles. **Example:** Calculate the RFM of water (H_2O). 1. Relative atomic mass of hydrogen (H) = 1.008 2. Relative atomic mass of oxygen (O) = 15.999 3. RFM of H_2O = $(2 \times 1.008) + (1 \times 15.999) = 18.015$

The Mole Concept: Bridging the Microscopic and Macroscopic

The mole (mol) is a unit of measurement representing 6.022×10^{23} ps (atoms, molecules, or ions). This seemingly abstract concept is critical for understanding chemical reactions and quantitatively relating macroscopic properties like mass to microscopic entities. **Example:** How many moles are there in 12 grams of carbon (C)? 1. Relative atomic mass of carbon = 12.011 2. Moles of carbon = $\text{mass}/\text{RAM} = 12\text{g} / 12.011 \text{ g/mol} = 0.999 \text{ mol}$ (approximately 1 mol)

Extension Questions: Molar Volume, Empirical Formulae, and Percentage Composition

Beyond basic calculations, extension questions often involve more complex scenarios. **1. Molar Volume:** One mole of any gas at standard temperature and pressure (STP, 0°C and 1 atm) occupies a volume of approximately 22.4 liters. This allows us to convert between volume and moles, as illustrated below. **Example:** What volume does 2 moles of oxygen gas occupy at STP? $\text{Volume} = \text{Moles} \times \text{Molar Volume} = 2 \text{ mol} \times 22.4 \text{ L/mol} = 44.8 \text{ L}$ **2. Empirical Formulae:** Empirical formulae represent the simplest whole-number ratio of atoms in a compound. Extension questions might require finding the empirical formula from experimental data like percentage composition or reacting masses. **Example:** A compound is 40% carbon, 6.7% hydrogen, and 53.3% oxygen by mass. Find the empirical formula. (Solution follows from calculating moles and ratios) **3. Percentage Composition:** This determines the percentage of each element in a compound by mass. Extension questions often involve calculating the percentage composition from the compound's formula or vice-versa. **Example:** What is the percentage composition of carbon in carbon dioxide (CO_2)? (Solution using RFM and relative atomic masses)

Real-Life Applications of Relative Mass and the Mole

These concepts are not confined to textbooks; they underpin many real-world applications:

- **Medicine:** Drug dosages are meticulously calculated to deliver the precise number of moles of active ingredients, ensuring effectiveness and minimizing side effects.
- **Manufacturing:** Industries use molar ratios to accurately determine the amounts of reactants needed to produce desired products. This efficiency prevents waste and minimizes costs.
- **Environmental Science:** Analyzing pollutants and determining their concentrations involves quantifying substances using the mole concept.
- **Food Science:** Baking recipes rely implicitly on molar ratios to adjust the amount of ingredients and ensure the right texture and taste.

Unlocking the Secrets of the Mole: Relative Mass and Extension Questions Answered

Ever found yourself staring at a chemistry textbook, a seemingly simple question about moles leaving you utterly bewildered? You're not alone! The concept of the mole, while fundamental to chemistry, can be a bit of a stumbling block for many. But what if we told you that understanding relative mass is the golden key to unlocking those tricky mole extension questions? That's right! By grasping how atomic and molecular masses relate to each other, you can navigate the world of chemical calculations with newfound confidence.

In this comprehensive guide, we're going to dive deep into the fascinating realm of relative mass and the mole. We'll break down the core concepts, tackle common extension questions, and provide clear, actionable answers to help you master this crucial aspect of chemistry. So, grab your thinking cap, and let's get started on this educational adventure!

The Foundation: Understanding Relative Mass

Before we even think about moles, we need to get a solid grip on what "relative mass" means. Think of it like comparing the weight of different objects to a standard. In chemistry, that standard is the carbon-12 atom.

Atomic Mass Units (amu)

Atoms are incredibly tiny, so measuring their masses in grams directly is impractical. Instead, we use a unit called the atomic mass unit (amu). One amu is defined as exactly one-twelfth ($1/12$) the mass of an unbound neutral atom of carbon-12. This might sound a bit technical, but it's just a way to create a consistent scale for atomic masses.

Relative Atomic Mass (A_r)

When we talk about the relative atomic mass of an element, we're essentially saying how many times heavier an atom of that element is compared to $1/12$ th of a carbon-12 atom. So, if an element has a relative atomic mass of 16, it means an atom of that element is 16 times heavier than $1/12$ th of a carbon-12 atom. You'll find these values listed on the periodic table – that's your handy cheat sheet!

Relative Molecular Mass (M_r) and Relative Formula Mass

This concept extends to molecules and ionic compounds. For molecules, the relative molecular mass (often denoted as M_r) is simply the sum of the relative atomic masses of all the atoms in that molecule. For example, the relative molecular mass of water (H_2O) is calculated by adding the relative atomic mass of two hydrogen atoms and one oxygen atom. Similarly, for ionic compounds that don't form discrete molecules, we use the term "relative formula mass," which is calculated in the same additive way for the ions in the formula unit.

The Star of the Show: The Mole

Now that we've got relative mass sorted, let's introduce the superstar: the mole. You can think of the mole as a chemist's "dozen." Just like a dozen means 12 of something, a mole represents a specific, very large number of particles.

Avogadro's Number: The Magic Number

This magical number is approximately 6.022×10^{23} particles (atoms, molecules, ions, etc.). This is known as Avogadro's number or Avogadro's constant. So, one mole of any substance contains 6.022×10^{23} of its constituent particles.

Molar Mass: Connecting Mass and Moles

Here's where relative mass and the mole beautifully intersect. The molar mass of a substance is numerically equal to its relative atomic or molecular mass, but it's expressed in grams per mole (g/mol). So, if an element has a relative atomic mass of 12 (like carbon), its molar mass is 12 g/mol. This means that 12 grams of carbon contains one mole of carbon atoms, or 6.022×10^{23} carbon atoms.

This relationship is absolutely crucial for calculations. It allows us to convert between the mass of a substance (which we can measure in the lab) and the number of moles (which tells us how many particles we have).

Diving into Extension Questions: Putting Knowledge to the Test

Now, let's tackle some common extension questions that often trip students up. These questions usually go beyond simple mole calculations and require a deeper understanding of the relationships between mass, moles, and particles.

Question Type 1: Calculating the Number of Atoms/Molecules in a Given Mass

Example: How many hydrogen atoms are there in 10 grams of water (H₂O)?

Breakdown:

- 1. Calculate the relative molecular mass of water:**
 1. Relative atomic mass of Hydrogen (H) ≈ 1.01
 2. Relative atomic mass of Oxygen (O) ≈ 16.00
 3. $M_r(\text{H}_2\text{O}) = (2 \times 1.01) + 16.00 = 2.02 + 16.00 = 18.02$
- 2. Calculate the molar mass of water:** This is numerically the same as the M_r , so it's 18.02 g/mol.
- 3. Calculate the number of moles of water:**
 1. $\text{Moles} = \text{Mass} / \text{Molar Mass}$
 2. $\text{Moles of H}_2\text{O} = 10 \text{ g} / 18.02 \text{ g/mol} \approx 0.555 \text{ moles}$
- 4. Calculate the number of water molecules:**
 1. $\text{Number of molecules} = \text{Moles} \times \text{Avogadro's Number}$
 2. $\text{Number of H}_2\text{O molecules} = 0.555 \text{ moles} \times 6.022 \times 10^{23} \text{ molecules/mol} \approx 3.34 \times 10^{23} \text{ molecules}$
- 5. Calculate the number of hydrogen atoms:** Each water molecule has 2 hydrogen atoms.
 1. $\text{Number of H atoms} = \text{Number of H}_2\text{O molecules} \times 2$
 2. $\text{Number of H atoms} = 3.34 \times 10^{23} \text{ molecules} \times 2 \text{ atoms/molecule} \approx 6.68 \times 10^{23} \text{ atoms}$

Key takeaway: Always remember to consider the number of atoms of a specific element within a molecule!

Question Type 2: Determining the Mass of a Given Number of Atoms/Molecules

Example: What is the mass of 3.011×10^{24} carbon atoms?

Breakdown:

- 1. Calculate the number of moles of carbon atoms:**
 1. $\text{Moles} = \text{Number of particles} / \text{Avogadro's Number}$
 2. $\text{Moles of C atoms} = (3.011 \times 10^{24} \text{ atoms}) / (6.022 \times 10^{23} \text{ atoms/mol}) = 5 \text{ moles}$
- 2. Find the molar mass of carbon:** From the periodic table, the molar mass of carbon is approximately 12.01 g/mol.
- 3. Calculate the mass of carbon:**
 1. $\text{Mass} = \text{Moles} \times \text{Molar Mass}$
 2. $\text{Mass of C atoms} = 5 \text{ moles} \times 12.01 \text{ g/mol} = 60.05 \text{ grams}$

Key takeaway: Work backwards from the number of particles to moles, and then to mass.

Question Type 3: Percentage Composition by Mass

Example: What is the percentage by mass of oxygen in sulfuric acid (H_2SO_4)?

Breakdown:

1. Calculate the relative molecular mass of sulfuric acid:

1. Relative atomic mass of Hydrogen (H) ≈ 1.01
2. Relative atomic mass of Sulfur (S) ≈ 32.07
3. Relative atomic mass of Oxygen (O) ≈ 16.00
4. $\text{Mr}(\text{H}_2\text{SO}_4) = (2 \times 1.01) + 32.07 + (4 \times 16.00) = 2.02 + 32.07 + 64.00 = 98.09$

2. Calculate the total mass of oxygen in the molecule:

1. Mass of O $= 4 \times 16.00 = 64.00$

3. Calculate the percentage by mass of oxygen:

1. Percentage of O $= (\text{Mass of O} / \text{Mr of H}_2\text{SO}_4) \times 100\%$
2. Percentage of O $= (64.00 / 98.09) \times 100\% \approx 65.24\%$

Key takeaway: This involves comparing the mass contribution of a specific element to the total mass of the compound.

Question Type 4: Empirical and Molecular Formulas

These questions often involve determining the simplest whole-number ratio of atoms in a compound (empirical formula) and then using that to find the actual number of atoms in a molecule (molecular formula), often with given molar mass information.

Example: A compound contains 40.0% carbon, 6.7% hydrogen, and 53.3% oxygen by mass. Its molar mass is 180.18 g/mol. What is its molecular formula?

Breakdown:

1. Assume a 100g sample: This makes the percentages directly into masses.

1. Carbon (C) = 40.0 g
2. Hydrogen (H) = 6.7 g
3. Oxygen (O) = 53.3 g

2. Convert masses to moles:

1. Moles of C $= 40.0 \text{ g} / 12.01 \text{ g/mol} \approx 3.33 \text{ moles}$
2. Moles of H $= 6.7 \text{ g} / 1.01 \text{ g/mol} \approx 6.63 \text{ moles}$
3. Moles of O $= 53.3 \text{ g} / 16.00 \text{ g/mol} \approx 3.33 \text{ moles}$

3. Find the simplest whole-number ratio (empirical formula): Divide each mole value by the smallest mole value (3.33 in this case).

1. C: $3.33 / 3.33 = 1$
2. H: $6.63 / 3.33 \approx 2$
3. O: $3.33 / 3.33 = 1$
4. Empirical formula: CH_2O

4. Calculate the empirical formula mass:

1. Empirical formula mass (CH_2O) $= 12.01 + (2 \times 1.01) + 16.00 = 12.01 + 2.02 + 16.00 = 30.03 \text{ g/mol}$

5. Determine the ratio of molecular formula mass to empirical formula mass:

1. Ratio $= \text{Molar Mass} / \text{Empirical Formula Mass}$
2. Ratio $= 180.18 \text{ g/mol} / 30.03 \text{ g/mol} \approx 6$

6. Multiply the subscripts in the empirical formula by this ratio:

1. Molecular formula $= (\text{CH}_2\text{O})_6 = \text{C}_6\text{H}_{12}\text{O}_6$

Key takeaway: This type of question combines percentage composition, mole calculations, and the concept of empirical and molecular formulas.

Understanding relative mass and the mole extension is foundational to mastering modern chemistry, bridging atomic-scale measurements with macroscopic observations. At its core, relative mass refers to the mass of a specific atom or molecule compared to a reference standard—most commonly carbon-12, assigned a mass of exactly 12 atomic mass units (amu). This reference allows scientists to express atomic weights in a consistent, practical way, enabling precise communication across scientific disciplines. While often simplified in early education, relative mass reveals deeper insights into chemical behavior, particularly when extended through the concept of the mole. The mole, defined as the amount of substance containing exactly 6.022×10^{23} elementary particles—atoms, molecules, or ions—serves as a powerful unit that transforms microscopic quantities into measurable, usable amounts. This extension of relative mass transforms abstract atomic weights into tangible values: knowing the relative mass of an element in amu allows students and researchers to calculate the exact mass of a given number of particles in grams. This connection between relative mass and the mole is not merely mathematical—it is essential for accurate laboratory work, from preparing chemical solutions to predicting reaction yields.

One of the most compelling insights from this concept is how it enables precise stoichiometric calculations. When chemists balance chemical equations, they rely on molar ratios derived from the mole concept, which are rooted in relative atomic and molecular masses. For instance, knowing that oxygen has a relative mass of approximately 16 amu helps determine that water, composed of two hydrogen atoms (1 amu each) and one oxygen, has a molar mass of 18 grams per mole. This direct relationship allows scientists to convert between grams and moles seamlessly, ensuring accurate dosing in pharmaceuticals, accurate concentrations in analytical chemistry, and reliable predictions in industrial processes.

Beyond the lab, the integration of relative mass and the mole extends into broader scientific and educational applications. In environmental science, tracking isotopic ratios using relative mass helps trace pollution sources or study climate change through carbon isotope analysis. In education, these concepts reinforce critical thinking by linking macroscopic measurements with atomic theory, helping students visualize how tiny particles scale up to real-world quantities. Moreover, this framework supports emerging fields such as materials science and nanotechnology, where precise control over atomic arrangements depends on accurate mass and mole calculations.

Looking ahead, the continued relevance of relative mass and the mole remains strong, even as analytical techniques evolve. As instruments grow more sensitive, the precision demanded by these fundamentals becomes even more critical. Innovations in spectroscopy and mass spectrometry deepen our ability to measure atomic masses with remarkable accuracy, reinforcing the reliability of relative mass as a cornerstone of quantification. Furthermore, as STEM education emphasizes conceptual understanding over rote memorization, teaching the mole as a bridge between relative mass and measurable substance ensures students grasp not just the “how” but the “why” behind chemical measurements. This enduring framework promises to support future scientific discovery, enabling clearer insights into molecular interactions, sustainable technologies, and the fundamental building blocks of matter.

Questions & Answers About relative mass and the mole extension questions answers

No	Question	Answer
1	Beyond calculating molar mass, how can we use the concept of the mole to predict the mass of reactants needed for a complete chemical reaction?	We use the mole concept and stoichiometry. First, balance the chemical equation to establish the mole ratios between reactants and products. Then, convert the desired mass of one substance to moles using its molar mass. Finally, use the mole ratios from the balanced equation to calculate the required moles of the other reactant, and convert that back to mass using its molar mass.
2	If I have a sample of a compound with a known mass, how can I determine the number of molecules present, going beyond just using the molar mass?	To find the number of molecules, you first calculate the number of moles by dividing the sample mass by the compound's molar mass. Then, you multiply the number of moles by Avogadro's number (approximately 6.022×10^{23} molecules/mol) to get the total number of molecules.
3	When dealing with isotopic abundance, how does the relative atomic mass impact the calculation of molar mass for a compound?	The relative atomic mass of an element is the weighted average of the masses of its isotopes. When calculating the molar mass of a compound, you use these weighted average relative atomic masses for each element, ensuring the final molar mass accurately reflects the natural abundance of isotopes in the compound.
4	What's the practical significance of the mole concept when you're not just doing calculations but need to understand chemical reactions on a larger scale?	The mole concept is fundamental for practical chemistry. It allows chemists to measure and mix substances in precise proportions for reactions. Without it, experiments would be unreliable, and large-scale industrial processes, like drug synthesis or fertilizer production, would be impossible to control accurately.
5	If two different substances have the same mass, does that mean they contain the same number of moles or molecules? Why or why not?	Not necessarily. While they have the same mass, they will only have the same number of moles and molecules if their molar masses are also the same. Different substances have different molar masses because their constituent atoms have different relative atomic masses and combine in different ratios.

In the realm of chemistry, understanding the fundamental concepts of mass, matter, and the quantities in which these exist is paramount. Two pivotal concepts that often intertwine, and can sometimes lead to confusion, are **relative mass** and **the mole**. While seemingly distinct, their relationship is symbiotic, forming the bedrock of quantitative chemistry. This article delves into the intricacies of relative mass and the mole, dissecting their definitions, applications, and the common extension questions that arise, providing detailed answers to solidify comprehension.

Understanding Relative Mass: The Building Blocks of Atomic Weight

Before we can truly grasp the mole, it's essential to have a firm grasp on relative mass. Essentially, relative mass is a comparison of the mass of one atom or molecule to the mass of a standard atom. Historically, different standards were used, but today, the international standard is the **atomic mass unit (amu)**, which is defined as one-twelfth the mass of a carbon-12 atom.

Atomic Mass and Relative Atomic Mass (Ar)

At the atomic level, the masses of individual atoms are incredibly small. Instead of using absolute mass values in grams, chemists work with **relative atomic mass (Ar)**. This dimensionless quantity represents the average mass of atoms of an element compared to 1/12th the mass of a carbon-12 atom. For instance, the Ar of hydrogen is approximately 1.008, meaning a hydrogen atom is about 1.008 times heavier than 1/12th of a carbon-12 atom. This concept is crucial for understanding isotopes and the weighted average of their abundances. When we look at the periodic table, the numbers listed under each element symbol are their relative atomic masses, often rounded for practical calculations.

Molecular Mass and Relative Molecular Mass (Mr)

Extending the concept of relative mass to molecules, we arrive at **relative molecular mass (Mr)**. This is simply the sum of the relative atomic masses of all the atoms in a molecule. For example, the relative molecular mass of water (H_2O) is calculated by taking twice the relative atomic mass of hydrogen plus the relative atomic mass of oxygen: $(2 \times 1.008) + 15.999 \approx 18.015$. Like Ar, Mr is a dimensionless quantity and is fundamental for stoichiometric calculations involving chemical reactions.

The Importance of Isotopes in Relative Mass

It's important to note that the relative atomic masses found on the periodic table are **weighted averages**. This is because most elements exist as isotopes – atoms of the same element with different numbers of neutrons, and therefore different masses. For example, chlorine exists as chlorine-35 and chlorine-37. The relative atomic mass of chlorine (approximately 35.45) reflects the relative abundance of these isotopes in nature. Understanding isotopes is a common extension question that requires a deeper dive into atomic structure.

The Mole: A Chemist's Counting Unit

While relative mass helps us compare the weights of atoms and molecules, the **mole** provides a practical way to quantify the number of particles (atoms, molecules, ions, etc.) in a given sample. It's analogous to how a "dozen" represents 12 of something, or a "ream" represents 500 sheets of paper. The mole is the SI unit for the amount of substance.

Avogadro's Number and its Significance

The number of particles in one mole of a substance is defined by **Avogadro's number**, which is approximately 6.022×10^{23} . This constant, denoted by N_A , is derived from experimental measurements and represents the number of entities in one mole. So, one mole of carbon atoms contains 6.022×10^{23} carbon atoms, and one mole of water molecules contains 6.022×10^{23} water molecules.

Molar Mass: The Bridge Between Mass and Moles

The crucial link between relative mass and the mole is **molar mass**. Molar mass is the mass of one mole of a substance and is numerically equal to the relative atomic mass (for elements) or relative molecular mass (for compounds) but expressed in grams per mole (g/mol). For example, the relative atomic mass of carbon is approximately 12.01. Therefore, the molar mass of carbon is 12.01 g/mol. This means that 12.01 grams of carbon contains 6.022×10^{23} carbon atoms. Similarly, the molar mass of water ($M_r \approx 18.015$) is 18.015 g/mol. This concept is indispensable for converting between mass and moles in chemical calculations.

Extension Questions and Answers: Mastering the Concepts

The interplay between relative mass and the mole often manifests in more complex problems. Here, we address some common extension questions and provide detailed answers.

Extension Question 1: Calculating the Number of Atoms in a Given Mass of an Element

Question: How many atoms are there in 50.0 grams of iron (Fe)?

Answer:

- Find the molar mass of iron:** From the periodic table, the relative atomic mass of iron is approximately 55.845. Therefore, the molar mass of iron is 55.845 g/mol.
- Calculate the number of moles of iron:** Number of moles = Mass / Molar mass
Number of moles = $50.0 \text{ g} / 55.845 \text{ g/mol} \approx 0.895$ moles
- Calculate the number of atoms:** Number of atoms = Number of moles $\times$ Avogadro's number
Number of atoms = $0.895 \text{ moles} \times 6.022 \times 10^{23} \text{ atoms/mol} \approx 5.39 \times 10^{23}$ atoms

Explanation: This question requires a two-step conversion. First, we use the given mass and the molar mass to determine the number of moles. Then, we multiply the number of moles by Avogadro's number to find the total number of atoms. This demonstrates the direct application of molar mass and Avogadro's number.

Extension Question 2: Determining the Mass of a Specific Number of Molecules

Question: What is the mass of 3.01×10^{24} molecules of glucose ($\text{C}_6\text{H}_{12}\text{O}_6$)?

Answer:

- Calculate the relative molecular mass of glucose:** $A_r(\text{C}) = 12.011$, $A_r(\text{H}) = 1.008$, $A_r(\text{O}) = 15.999$
 $M_r(\text{C}_6\text{H}_{12}\text{O}_6) = (6 \times 12.011) + (12 \times 1.008) + (6 \times 15.999)$
 $M_r(\text{C}_6\text{H}_{12}\text{O}_6) = 72.066 + 12.096 + 95.994 \approx 180.156$
- Calculate the molar mass of glucose:** The molar mass of glucose is 180.156 g/mol.

- Calculate the number of moles of glucose:** Number of moles = Number of molecules / Avogadro's number
 $\text{Number of moles} = (3.01 \times 10^{24} \text{ molecules}) / (6.022 \times 10^{23} \text{ molecules/mol}) \approx 5.00 \text{ moles}$
- Calculate the mass of glucose:** Mass = Number of moles $\times$ Molar mass
 $\text{Mass} = 5.00 \text{ moles} \times 180.156 \text{ g/mol} \approx 900.78 \text{ grams}$

Explanation: Here, we are given the number of molecules and need to find the mass. This involves first calculating the molar mass of the compound using its molecular formula and relative atomic masses. Then, we use Avogadro's number to convert the number of molecules into moles, and finally, multiply by the molar mass to get the mass in grams. This question highlights the process of determining molar mass from atomic masses.

Extension Question 3: Determining the Number of Atoms of a Specific Element within a Compound

Question: How many oxygen atoms are there in 100.0 grams of sulfuric acid (H_2SO_4)?

Answer:

- Calculate the relative molecular mass of sulfuric acid:** $\text{Ar}(\text{H}) = 1.008$, $\text{Ar}(\text{S}) = 32.06$, $\text{Ar}(\text{O}) = 15.999$
 $\text{Mr}(\text{H}_2\text{SO}_4) = (2 \times 1.008) + 32.06 + (4 \times 15.999)$
 $\text{Mr}(\text{H}_2\text{SO}_4) = 2.016 + 32.06 + 63.996 \approx 98.072$
- Calculate the molar mass of sulfuric acid:** The molar mass of sulfuric acid is 98.072 g/mol.
- Calculate the number of moles of sulfuric acid:** Number of moles = Mass / Molar mass
 $\text{Number of moles} = 100.0 \text{ g} / 98.072 \text{ g/mol} \approx 1.0197 \text{ moles}$
- Determine the number of moles of oxygen atoms:** In one molecule of H_2SO_4 , there are 4 oxygen atoms. Therefore, in 1.0197 moles of H_2SO_4 , there are:
 $\text{Moles of O atoms} = \text{Moles of H}_2\text{SO}_4 \times 4$
 $\text{Moles of O atoms} = 1.0197 \text{ moles} \times 4 \approx 4.0788 \text{ moles}$
- Calculate the number of oxygen atoms:** Number of O atoms = Moles of O atoms $\times$ Avogadro's number
 $\text{Number of O atoms} = 4.0788 \text{ moles} \times 6.022 \times 10^{23} \text{ atoms/mol} \approx 2.456 \times 10^{24} \text{ atoms}$

Explanation: This question involves finding the number of atoms of a *specific element* within a compound. We first determine the molar mass of the compound and then the number of moles of the compound. The key step is then using the stoichiometric ratio from the chemical formula to find the number of moles of the element in question. Finally, Avogadro's number is used to convert moles of atoms to the number of atoms. This tests the understanding of chemical formulas and their relationship to molar quantities.

Extension Question 4: Empirical and Molecular Formulas and Moles

Question: A compound contains 40.0% carbon, 6.7% hydrogen, and 53.3% oxygen by mass. If the molar mass of the compound is 180.0 g/mol, what is its molecular formula?

Answer:

- Assume a 100 g sample:** This allows us to treat the percentages as grams. Mass of C = 40.0 g Mass of H = 6.7 g Mass of O = 53.3 g
- Convert masses to moles:** Moles of C = $40.0 \text{ g} / 12.011 \text{ g/mol} \approx 3.33 \text{ moles}$ Moles of H = $6.7 \text{ g} / 1.008 \text{ g/mol} \approx 6.65 \text{ moles}$ Moles of O = $53.3 \text{ g} / 15.999 \text{ g/mol} \approx 3.33 \text{ moles}$
- Determine the empirical formula:** Divide each mole value by the smallest mole value (3.33). C: $3.33 / 3.33 = 1$ H: $6.65 / 3.33 \approx 2$ O: $3.33 / 3.33 = 1$ The empirical formula is CH_2O .
- Calculate the empirical formula mass:** Empirical formula mass = $\text{Ar}(\text{C}) + 2 \times \text{Ar}(\text{H}) + \text{Ar}(\text{O})$
 $\text{Empirical formula mass} = 12.011 + (2 \times 1.008) + 15.999 \approx 30.026 \text{ g/mol}$
- Determine the molecular formula:** Ratio = Molar mass / Empirical formula mass
 $\text{Ratio} = 180.0 \text{ g/mol} / 30.026 \text{ g/mol} \approx 6$ The molecular formula is $(\text{CH}_2\text{O})_6$, which simplifies to $\text{C}_6\text{H}_{12}\text{O}_6$.

Explanation: This question integrates the concepts of percent composition, empirical formula, molecular

formula, and molar mass. By determining the simplest whole-number ratio of atoms in a compound (empirical formula) and then comparing its mass to the given molar mass, we can deduce the actual molecular formula. This type of problem is fundamental in identifying unknown compounds.

Conclusion: A Unified Framework for Quantitative Chemistry

Relative mass and the mole are not isolated concepts; they are intrinsically linked, forming a unified framework for quantitative chemistry. Relative atomic and molecular masses provide the foundation for understanding the composition of matter at the atomic and molecular level. The mole, with Avogadro's number, offers a practical unit for counting these particles, and molar mass serves as the crucial bridge between mass and the number of moles. Mastering these concepts and their application in solving extension questions unlocks the ability to perform accurate stoichiometric calculations, predict reaction yields, and understand the quantitative aspects of chemical processes. A solid understanding of these fundamental building blocks is essential for anyone pursuing a deeper understanding of chemistry.
